The management of cultural heritage and landscape in inner areas

edited by Mara Cerquetti, Leonardo J. Sánchez-Mesa Martínez, Carmen Vitale

Guardo le canoe che fendono l'acqua, le barche che sfiorano il campanile, i bagnanti che si stendono a prendere il sole. Li osservo e mi sforzo di comprendere. Nessuno può capire cosa c'è sotto le cose. Non c'è tempo per fermarsi a dolersi di quello che è stato quando non c'eravamo. Andare avanti, come diceva Ma', è l'unica direzione concessa. Altrimenti Dio ci avrebbe messo gli occhi di lato. Come i pesci¹.

Quando cammino nei prati attorno al Santuario, quasi sempre solo, ripenso a nonno Venanzio che, da giovane biscino, pascolava il gregge negli stessi terreni. Mi affascina il fatto che in questo luogo la cui cifra, agli occhi di chi guarda adesso la mia scelta di vita, è la solitudine, nei secoli addietro abitassero oltre duecento persone. Ancora negli anni Cinquanta, ricorda mio nonno, erano quasi un centinaio gli abitanti di Casette di Macereto tra contadini, mezzadri, mogli, pastori e un nugolo di bambini che costringeva il maestro a salire ogni giorno da Visso per fare lezione a domicilio.

Era una comunità compatta, coordinata come lo può essere quella delle società operose degli insetti: api, formiche, tremiti, ma cosa più sorprendente che mai, una comunità niente affatto statica o chiusa².

Information system for the management of the Archaeological Map of Macerata Province: the archaeological potential map as a tool for the management of the archaeological heritage and territorial planning of the inner areas

Chiara Capponi*

Abstract

The research is aimed at creating a map of archaeological risk and a map of archaeological potential for the province of Macerata. The exam of the data of the Archaeological Map of Macerata province highlights different degrees of information, which depend on the context(s) of discovery and the level of analysis. The adoption of Geographic Information Systems (GIS) for the archaeological data and the management of the same in a Territorial Information System (SIT) allow the creation of models for spatial analysis. These models, applied to a territory for which archaeological data are insufficient, might be useful in interpreting settlement patterns and archaeological processes in a given area. Particular attention was paid to the geological information. The analysis of all the data archived in the SIT, which will certainly suggest new research topics to deepen, is already advantageous in the governance and strategic development of the territory, particularly in the inner areas.

* Chiara Capponi, PhD student in Linguistic, philological, literary studies, University of Macerata, Department of Humanities, Corso Cavour, 2, 62100 Macerata, e-mail: c.capponi@studenti.unimc.it.

Nel contributo è dettagliata la metodologia applicata alla ricerca finalizzata alla creazione della carta del rischio e della carta di potenzialità archeologica della provincia di Macerata con particolare riguardo alle aree interne. L'esame dei dati archeografici evidenzia differenti gradi di informazione determinati dalla tipologia del ritrovamento archeologico e dall'intensità della ricerca. L'archiviazione in ambiente GIS dei dati archeologici e la successiva gestione degli stessi in un sistema informativo territoriale (SIT) consentono la creazione di modelli per analisi spaziali. Tali modelli, proiettati nei territori per i quali le informazioni archeologiche sono scarse o nulle, rappresentano la base per la valutazione storica delle modalità insediative e di sfruttamento del territorio nel suo complesso. Particolare attenzione è rivolta alle informazioni geologiche. L'analisi e la rielaborazione di tutti i dati all'interno di un SIT, permettendo di creare differenti tematismi, si presenta particolarmente utile nelle aree interne per tutte le scelte progettuali legate alla *governance*, allo sviluppo del territorio e alla pianificazione intersetoriale.

The research is part of the CAM project (Marche Archaeological Map), supported by the Marche Region and lead, for the province of Macerata, by Roberto Perna of the University of Macerata, in cooperation with the Province of Macerata, the Macerata Museum System association and the Marche Archaeology, Fine Arts and Landscape Superintendency Department¹. This ongoing study has been carried out during the Ph.D. in Linguistic, philological, literary studies (XXXI Cycle, EUREKA course) in collaboration with PlayMarche s.r.l., a spin-off of the University of Macerata. The research is aimed at creating a map of archaeological risk and the map of archaeological potential for the area in the province of Macerata by developing simulation models and relative projections that produce graphic depictions of the territorial areas most suited to stable settlement under the form of “risk ranges”².

A territorial information system has been created for this end organised on the following different databases and charts:

- regional technical map (CTR)³;
- colour digital orthophoto map⁴;

¹ Perna 2001, 2002; Perna, Orsetti 2001; Capponi, Perna 2012.

² The branch of spatial analysis and simulation with the prediction of archaeological “risk” was developed early parallel with the development of mathematical-statistical surveys applied to geography, urban sociology and similar subjects (see Azzena 1987 and 2009; Fabiani *et al.* 2013; Gelichi 2008; Moscati 1998, 2013). Regionally, this is the first experiment on a vast scale; similar studies have been prepared for limited portions of land: Ascani *et al.* 2004; Perna 2004a, 2004b, 2006.

³ The reference map basis used is regional maps (CTR) for the province of Macerata on the scale of 1:10,000. The reference geodetic map system is “Gauss-Boaga Fuso Est” (Code EPSG3004), with the geodetic reference based on the international ellipsoid directed towards Monte Mario (Rome 1940).

⁴ Colour digital orthophoto map of the province of Macerata on a scale of 1:10,000 with updated to the year 2010, created by the Agency for funding in agriculture (AGEA) following an agreement signed in 2010 with the Marche Region.

- map of the use of land⁵;
- regional environmental landscape plan⁶;
- geological map of the Marche Region and soil map of the provinces;
- SIRPaC database of the archaeological map for the province of Macerata;
- geographical/spatial unit regarding the areas subject to archaeological restriction;
- DB regarding historical roads.

1. Geology and geomorphology

This research is based on the assumption that the site vocation and the possibility of finding archaeological deposits largely also depend on the territory's geomorphology. The geomorphological data was crossed with the study of the area's historical evolution, as in the choice of areas allocated for various types of land occupation, accessibility of resources, above all water, the road system, proximity to an important urban centre or an important place of worship take on significant roles. Man's wishes constitute a primary source in the decision of which areas to settle in, respecting the potential that the environment offers and also via a selection of the most suitable places, that is not necessarily repeated in the same way in all eras and in all areas.

2. Archaeological map database for the province of Macerata

This database collects all the news regarding archaeological evidence found from bibliographical and archive collections (starting with the Marche Superintendency's archives)⁷. The CAM data collected in the 2000 and 2003 study campaigns, promoted directly by the Marche Region and in the 2007, 2010 and 2011 campaigns supported by the Province of Macerata, specifically by the catalogue centre of the province of Macerata Museum System association, was integrated with the data from recent research to develop the SIT. More specifically, the data have been implemented, with the results from studies carried out by the Department of Humanities, the former S.A.S.A. (Archaeological Science and

⁵ The Region's map of the use of land (stages completed 2007) on a scale of 1:10,000.

⁶ PPAR (Regional Environmental Landscape Plan), in detail: Tab. 2 – Morphological groups; Tab. 3A – Geological emergencies; Tab. 10 – Archaeological and historical remembrance places; Tab. 13 – Geomorphological emergencies; Tab. 17 – Archaeological sites of interest that have been outlined on maps. Future implementations may foresee the inclusion of the PRG (Regional General Plan) and the PTC (Territorial Coordination Plans), regarding the province of Macerata.

⁷ Archaeological pieces of evidence between the Palaeolithic and the Late Antique (600 AD).

Ancient History Department) at the University of Macerata⁸. Edited data from the University of Ghent's PVS project⁹ and the R.I.M.E.M. project directed by Professor Umberto Moscatelli from the University of Macerata¹⁰ have also been entered. Collaboration with the Archaeological Superintendency Department allowed the entry of information about all archaeological interventions digs and/or assistance up to the year 2016¹¹.

The creation of the known map, where the various findings have been located and visualised, was the premise on which the study was based. This action provided an analysis of archaeological knowledge in the Province of Macerata to date. There are different degrees of information present, determined by the type of archaeological finding (casual discovery, planned excavation, emergency excavation, reporting) and the intensity of the search. Direct surveys, with topographical recognition, that were conducted as part of diversified projects, were only carried out on some part of the provincial area and are more limited in internal areas where accessibility and visibility conditions are not as favourable due to the presence of elevations, steep slopes, woodland or uncultivated areas¹². The municipalities that fall into this area are Apiro, Belforte del Chienti, Calderola, Camerino, Camporotondo di Fiastrone, Castelraimondo, Castelsantangelo sul Nera, Cessapalombo, Cingoli, Colmurano, Esanatoglia, Fiastra, Fiuminata, Gagliole, Loro Piceno, Matelica, Montecavallo, Muccia, Penna San Giovanni, Pievetorina, Pioraco, Poggio San Vicino, Ripe San Ginesio, San Ginesio, Sarnano, Sant'Angelo in Pontano, Sefro, Serrapetrona, Serravalle di Chienti, Tolentino, Ussita, Valfornace and Visso (see the list of archaeological sites in tab. 1).

3. Archiving archaeological data in a GIS environment

The original archaeological data were registered in the SI (Archaeological Site) sheets (Si.mdb) in the SIRPaC software (*Sistema Informativo Regionale del Patrimonio Culturale*/Regional Information System of Cultural Heritage)

⁸ Capponi Perna 2012; Perna 2012a, 2012b, 2012c, 2014, 2015, 2018; Perna *et al.* 2014.

⁹ Percossi *et al.* 2006; Vermeulen *et al.* 2017.

¹⁰ Moscatelli 2013, 2015.

¹¹ It has also been possible to consult current archives at the Marche Archaeological Superintendency Department and documents kept in the Dossier archive.

¹² The municipalities involved in the systematic surveys to date are Cingoli (Calvelli 1999 and work thanks to the research by Alberto Calvelli, unpublished), Calderola, Cessapalombo, San Ginesio, Valfornace (portions of the land in these municipalities are included in the R.I.M.E.M. project), Serravalle del Chienti and Camerino, the subject of surveys by Dr. Bonomi Ponzi (1992); Matelica with studies by Dr. Biocco (Biocco 2000, 2009); Castelraimondo, Camerino, Fiuminata and Pioraco that are involved in the PVS project; Tolentino and Loro Piceno included in the CAM project by the Department of Humanities of the University of Macerata.

developed with Microsoft Access from the Marche Region¹³. As this research is the continuation of the previous CAM project, which was developed in a Windows environment, we continued with this choice in order to ensure compatibility with the bodies participating in the project, such as the Marche Archaeology, Fine Arts and Landscape Superintendency Department, the Marche Region and the Department of Humanities at the University of Macerata. This research, therefore, does not use a dedicated relational database. The simple, rapid interface from the SIRPaC Programme, the verification procedures for the mandatory nature of fields and terminology dictionaries were used.

The SIRPaC, developed according to the standards of the ICCD (Central Institute for the Catalog and Documentation), allows the export of data in two tracks:

- *.trc for data transfer;
- *.cbc an extended path.

The site sheets (SI) for known archaeological presences in the provincial area provide multiple data which was selected by migrating information into the layer file attributes table, named Archaeological Map. We worked directly on the QGis database for implementation. Additional fields were entered on the layer file attributes table (fig. 1).

The selected information was about:

- the type of archaeological evidence, divided into type, macrotype, definition and description;
- geographic location divided into area it belongs to, municipality, location, placement reliability, coordinates.

Implementation concerned the chronological information that could not be directly migrated as the field provides for the possibility of repeating data entry if the archaeological evidence spans a very broad period of time¹⁴. Likewise, implementation of the tables was necessary to enter information about the depth of the archaeological presences, as the data, where present, was contained in free descriptions provided for by the SIRPaC database, therefore in a non-usable mode. All the archaeological data have been georeferenced according to the rate of reliability, which led to the choice of geometries to be used during data entry. To position the archaeological findings in the reference geomorphological context, it was necessary to separate the archaeological evidence that can reliably be located from the others. The sites with “precise” or “good” location were restored in their actual territorial size, using the polygonal graph when the extension exceeded a diameter of 30 metres. All the historical-archaeological data that does not lead to providing the perimeter of an archaeological area,

¹³ Perna 2001; Baldelli *et al.* 2004.

¹⁴ Archiving of the chronological data in a GIS environment is one of the most difficult aspects of managing data. On the structuring of chronological data in the SIRPaC programme and their use in a GIS environment, see Gnesi *et al.* 2007, pp. 122-125.

but which is useful historical-archaeological data for producing the potential map, are arranged as “finding reports” and are shown on a point graph (fig. 2).

4. Planning the SIT and the changeover to an AIS (Archaeological Information System)

Planning the SIT involved data entry, processing a spatial database and subsequent manipulation and analysis. The platform was created using QGis 2.1.8. “Las Palmas”. QuantumGIS is a software free and open-source (FOSS)¹⁵. The software allows you to create, edit, visualise, analyse and publish geospatial information. Its main features are the management of geometrical data, the ability to georeference all the data, the ability to characterise all registered data and thematic or spatial search potential. The input files were managed in a geodatabase as a feature-class that can be exported in shapefile format (.shp)¹⁶.

The geodatabase contains:

- the description of the environment (basic map dataset, dataset orthophoto map, dataset use of land, dataset modern road system);
- geological description (geomorphology dataset, geopedology dataset, PAI dataset);
- archaeological description (archaeological map dataset, historical road dataset, dataset of areas subject to archaeological restriction).

All the system information has been processed and encoded for each thematism (horizontal mode) and for joint thematisms on the same geographic area (vertical mode). The purpose is to process all the information about the archaeological sites, the risk sources and the geomorphological characteristics in order to provide diversified information according to the different types of evaluation necessary. The Boolean overlapping of thematic maps, the calculation of statistic correlations between environmental information and sites and the predictive analyses combined into a single work tool suggest a definition of this AIS (Archaeological Information System) research.

Its principal functions are:

- information archiving and processing;
- production of information and data reading;
- support for analysing and making decisions or planning interventions.

¹⁵ The QGIS is a project of the Open Source Geospatial Foundation (OSGeo) and is under development by a developer community: <<https://qgis.org/>>, 01.04.2019.

¹⁶ Shapefile has three main files that contain both spatial information and the attributes of a database file. This format was made public by ESRI, the company that developed it, in order to provide data swapping between different systems. ESRI Shapefile technical description: <<http://www.esri.com/library/whitepapers/pdfs/shapefile.pdfs>>, 01.04.2019.

5. The archaeological risk map

To process the evaluation of risk, it is necessary to outline the risk sources that lead to the vulnerability of findings. The actions that interact with archaeological sites are split into:

- anthropic actions (in this case, the following have been taken into consideration: construction expansion areas, areas close to main roads);
- natural actions (in this case, the following were taken into consideration: flooding areas, landslide areas).

The archaeological risk map has been organised on three levels. The first level provides an evaluation of the archaeological site's state and historical-cultural value¹⁷. The parameters taken into consideration refer to the type of site, its interpretability and its continuity. Specifically, archaeological sites have been categorised as follows:

- outcrop areas category vulnerability 1;
- areas with structures (civil, funerary, productive) category vulnerability 2;
- settlements category vulnerability 3;
- conservative habitats (municipium, colony) category vulnerability 4;

The second level identifies archaeological site exposure to the level of vulnerability, analysing the spatial distribution of sources of risk and their possible joint presence. It is thus possible to highlight site exposure to current anthropic or natural risk sources, and to highlight the dependency on one or more modern risk sources and consequently produce a scale of exposure to risk. The risk is at its maximum when all 4 risk sources are present and none of them is absent (figs. 3-5).

The third level evaluates the risk value for each site, through the simultaneous analysis of both the state of conservation and exposure to risk sources.

In other words, considering risk as the product between the site's state of conservation and its exposure to damage sources, it is possible to generate a list of sites, according to the risk to which they are subjected.

6. The archaeological potential map

A predictive approach was used with this analysis, that allowed the archaeological risk to be integrated with archaeological potential. This type

¹⁷ In this research, it was not possible to associate the concept of vulnerability with the archaeological site's state of conservation to the lack of data on the structural deterioration of archaeological evidence. For the census of the archaeological heritage of the province of Macerata in the Risk Map produced by the Istituto Superiore per la Conservazione (formerly ICR), please refer to the website <<http://www.cartadelrischio.it/>>, 01.04.2019.

of map presumes an overall optimisation of the territory, as the identification of particular characters of the territory to be associated with a historical-archaeological study is at the basis of it. A cross-analysis of the archaeological presences and the morphological data was carried out for this purpose. The archaeological sites were selected according to their reliability rate; the evidence with exact or good location was taken into consideration for the study. The range of each site was expanded with a minimum buffer area allocated according to the type of site (fig. 6).

Historical roads and preserved centuriel limits were considered in the dataset; in this case too, a minimum distance was created, a buffer zone of 50 metres for roads and 25 metres for centuriel persistence.

A statistical spatial analysis was then carried out using the Kernel Density Estimation (KDE) method from the Point Pattern Analysis method, via the Q-GIS Heatmap tool, and the buffer analysis in order to create statistical maps that are related to the geophysical characteristics of the territory¹⁸.

With regards to the internal areas of the province of Macerata, only a small part of the Apennine territory was frequented or settled in (fig. 6). Erosions and hydrogeological instability in this mountainous area may have caused the moving or disappearance of archaeological deposits that are mostly on the surface. Archaeological data that is suitable for analysis and processing come from the municipalities of Camerino, Castelraimondo, Cingoli, Loro Piceno, Matelica, Muccia, San Severino Marche, Serravalle del Chienti, Tolentino, Valfornace. Archaeological information in these areas varies in type and chronology and the forms of population and use of the land can be associated with the distribution of some artificial elements of the landscape, such as the centuriel main roads, road networks and natural internal penetration routes, as well as the presence of dominant centres, including the ones allocated for the practice of worship¹⁹. In the municipalities of Castelsantangelo sul Nera, Esanatoglia, Fiastra, Fiuminata, Montecavallo, Sefro, Ussita and Visso with their high altitude and elevations of more than 1000 metres above sea level, archaeographic data, which is limited and refers almost exclusively to news of casual findings rarely located with certainty, can be used to check the data produced in the initial analysis²⁰.

¹⁸ On Point Pattern Analysis see Hodder, Orton 1976, p. 30. For the determination of radius see Conolly, Lake 2006, p. 186. The method used has been adopted by the Mappa project: Fabiani *et al.* 2013.

¹⁹ See the list of archaeological sites on this matter. For details of each archaeological evidence and for the analysis of historical roads, please refer to the Province of Macerata Archaeological Map currently being printed. For sites of worship see Perna *et al.* 2013.

²⁰ To date, no archaeological sites are known for the municipalities of Bolognola, Gualdo and Monte San Martino.

7. Future outlook: the archaeological potential map as a governance tool

The archaeological potential map is an alternative to the so-called emergency archaeology, intended as a dig started up when the threat of destruction becomes clear for the archaeological item. This tool is a part of preventive archaeology actions, in fact, and corresponds to the contents of the document produced by the Ministerial Commission for creating the archaeological information system of Italian cities and their territories²¹.

At the same time, the traditional interpretation of archaeological landscape, and sets of sites is overcome, around which a minimum distance is recognised²² as the areas where archaeological presences are predictively located are restored alongside the known archaeological areas. The instrument is especially useful for internal areas where known archaeological testaments are conditioned primarily by the geophysical characteristics of this territory; characters that have affected direct archaeological research in the field over the years.

In order to include it in the territorial planning actions, each archaeological site that is analysed or “reconstructed” will be assigned, in accordance with the Marche Region and the Archaeological Superintendency Department, a protection category to be added to the ones already stated in the PPR (Regional Environmental Landscape Plan)²³. With regard to archaeological heritage, to date only the area of archaeological interest bound pursuant to art. 142/letter m of the Code of Cultural Heritage and Landscape are considered in the PPAR²⁴. The instruments of the local restriction, drawn up by the Ministry, are not sufficient for the actions of protection and safeguarding of the widespread archaeological heritage.

The area of archaeological respect, including a band of “conditioned protection”, aimed at correct understanding and safeguarding can be classified

²¹ On 24 January 2007, the Minister for Cultural Heritage of the time, Francesco Rutelli, appointed the preparatory commission for creating the Archaeological Information System of Italian cities and their Territories, chaired by Andrea Carandini, with the result being a final report that can be consulted in Carandini 2008 (pp. 199-207). On the one hand, the document highlights the lack of coordination among the various research activities aimed at creating archaeological territorial information supports (for further information on this matter, see Azzena 2009); on the other hand, it supports the necessary collaboration between universities, to which knowledge of protection and optimisation is transferred, the State to which protection “illuminated by knowledge, regulated by uniform procedures and aimed at optimisation and fruition” is transferred and the Regions and other territorial bodies for planning, optimisation and fruition. Collaboration already promoted by the Legislative Decree 42/2004, “Code of Cultural Heritage and Landscape”, art. 1, par. 3 and art. 5.

²² On this matter Brogiolo 2009.

²³ Law 8 August 1985, No. 431 and Regional Law 8 June 1987, No. 26. Approved by Administrative Resolution 3 November 1989, No. 97, currently under review.

²⁴ Legislative Decree 22 January 2004, No. 42, pursuant to art. 10 of Law 6 July 2002, No. 137. The Web Gis of Landscape Heritage has been available since February 2017 at the link <<http://ctr.regione.marche.it/BP/default.aspx>>, 01.04.2019.

according to the configuration and size in at least 4 subcategories, to which specific prescriptions should be associated:

- category a: archaeological complexes subject to restriction;
- category b: areas of ascertained and relevant archaeological size, areas with considerable presence of materials (settlements, necropolises, production and agricultural structures, portions of roads, aqueduct ruins), that have already been found or that are not yet touched by regular archaeological excavations;
- category c: concentrated areas of archaeological materials or report of findings; areas of respect or integration or safeguarding of paleo-habitats, sample areas for the conservation of particular statements of types and archaeological sites; areas with considerable archaeological risk;
- category d: areas with archaeological potential, divided in turn into high, medium and low potential.

The aim of this study is to provide all the necessary, useful data for the planning and management of administrative, management and tourist-cultural interventions. The archaeological potential map could, therefore, run alongside current tools, to provide additional information for a historical understanding of the territory and to favour territorial planning actions, the only useful instrument for safeguarding this widespread heritage. In this sense, the methodological tool that this research embraces is global archaeology that does not recognise the historical value of each site but of the anthropic landscape overall, abiding by the European Landscape Convention guidelines²⁵.

Appendix

ARCHAEOLOGICAL MAP LAYER FIELDS	
MARK	DESCRITPION
ID	sequential number
NCTN	identification number
CRBC	catalog number
PVCP	administrative area
PVCC	municipality
PVCL	locality
AFF	degree
OGTS	type
OGTM	macrotype
OGTD	definition
OGTX	depscription
VUL	vulnerability
QUOT	depth
DTPA	Paleolithic/Mesolithic
DTNE	Neolithic
DTEN	Eneolithic
DTBR	Bronze Age
DTFE1	Iron Age 1
DTFE2	Iron Age2
DTRE	Roman Republican Age
DTIM	Roman Imperial Age
DTTA	Late Antiquity

Tab. 1. List of archaeological sites, divided by municipality with a list of the types of evidence, damage, and degree of placement reliability

Types of evidence:

BS = bibliography source

AS = archive source

SAR = surface archaeological remains

S = structure

UC = urban center

TS = toponymy source

SET = settlement

Degree of placement:

G = good

E = exact

M = mediocre

A = approximate
